- In this talk, we discuss some problems and properties of visibility graphs of point sets in the plane.
- Visibility graphs are widely studied structures in computational geometry, and may be defined on point sets, line segments, polygons and other geometric sets.
- Visibility graphs have their use in robot motion planning, security problems etc.

 $P = \{p_1, p_2, \dots, p_n\}$ is a given set of points on the plane.

Two points p_i and p_j of P are *mutually visible* if the line segment $p_i p_j$ does not contain or pass through any other point of P.

Two points p_i and p_k of P are *mutually invisible* if the line segment $p_i p_i$ contains or passes through another point of P.

A point p_j of P lying on the line segment $p_i p_k$, is called a *blocker* of p_i and p_k .

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

The point visibility graph (PVG) of P is a graph G = (V, E), s.t. $v_i \in V \Leftrightarrow p_i \in P$, and $v_i v_j \in E \Leftrightarrow p_i$ and p_j are mutually visible (Ghosh, 2007, Ghosh et al, 2010).

$$\begin{split} &G(V,E):\\ &V=\{v_1,v_2,v_3,v_4,v_5,v_6,v_7,v_8,v_9\}\\ &E=\{(v_1,v_2),(v_1,v_3),(v_1,v_4),(v_1,v_5),\\ &(v_2,v_3),(v_2,v_4),(v_2,v_5),(v_2,v_6),(v_2,v_9),\\ &(v_3,v_4),(v_3,v_7),(v_3,v_8),(v_3,v_9),\\ &(v_4,v_5),(v_4,v_7),(v_4,v_8),\\ &(v_5,v_6),(v_5,v_7),(v_5,v_9),\\ &(v_6,v_7),(v_6,v_8),(v_6,v_9),\\ &(v_7,v_8),(v_7,v_9),\\ &(v_8,v_9)\} \end{split}$$

The point visibility graph (PVG) of P is a graph G = (V, E), s.t. $v_i \in V \Leftrightarrow p_i \in P$, and $v_i v_j \in E \Leftrightarrow p_i$ and p_j are mutually visible (Ghosh, 2007, Ghosh et al, 2010).

$$\begin{split} &G(V,E):\\ &V=\{v_1,v_2,v_3,v_4,v_5,v_6,v_7,v_8,v_9\}\\ &E=\{(v_1,v_2),(v_1,v_3),(v_1,v_4),(v_1,v_5),\\ &(v_2,v_3),(v_2,v_4),(v_2,v_5),(v_2,v_6),(v_2,v_9),\\ &(v_3,v_4),(v_3,v_7),(v_3,v_8),(v_3,v_9),\\ &(v_4,v_5),(v_4,v_7),(v_4,v_8),\\ &(v_5,v_6),(v_5,v_7),(v_5,v_9),\\ &(v_6,v_7),(v_6,v_8),(v_6,v_9),\\ &(v_7,v_8),(v_7,v_9),\\ &(v_8,v_9)\} \end{split}$$

Given a point set *P* in the plane, its *PVG* can be computed in $O(n^2)$ time by using the results of Chazelle et al. (1985) or Edelsbrunner et al. (1986).

Given a point set P in the plane, its PVG can be computed in polynomial time.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Given a point set P in the plane, its PVG can be computed in polynomial time.

Problem definition:

Given a graph G, is there a point set P on the plane such that G is the PVG of P?

<ロト 4 目 ト 4 日 ト 4 日 ト 1 日 9 9 9 9</p>

Given a point set P in the plane, its PVG can be computed in polynomial time.

Problem definition:

Given a graph G, is there a point set P on the plane such that G is the PVG of P?

The above problem is called the *recognition* problem for *PVGs*.

<ロト 4 目 ト 4 日 ト 4 日 ト 1 日 9 9 9 9</p>

Given a point set P in the plane, its PVG can be computed in polynomial time.

Problem definition:

Given a graph G, is there a point set P on the plane such that G is the PVG of P?

The above problem is called the *recognition* problem for PVGs. Such a point set, if it exists, is called a *visibility embedding* of G.

Results:

- ► Ghosh and Roy (2015) provided the following.
 - (a) Three necessary conditions for recognizing PVGs,
 - (b) They showed that the recognition problem for PVGs is in PSPACE,
 - (c) They gave a complete characterization, and using the characterization they designed a linear time algorithm for the recognition of planar PVGs.

Results:

- Roy (2016) showed that the recognition problem for PVGs in general is NP-hard.
- ► Cardinal and Hoffman (2017) concluded the problem by showing that the recognition problem for PVGs is complete in ∃R (exist reals).

The reduction

 We discuss the NP-hardness of the recognition problem of PVGs (Roy, 2016).

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

The reduction

- We discuss the NP-hardness of the recognition problem of PVGs (Roy, 2016).
- ► For the proof, we reduce 3-SAT to the recognition problem.

Start with an $n \times n$ slanted grid graph.

Modifying the slanted grid graph

Delete a subgrid of $m_0(n-2)$ vertices, $m_0 \leq (n-2)$, for embedding the 3-SAT graph later.

・ロト ・ 日 ・ ・ 田 ト ・ 日 ト ・ 日 ト

Modifying the slanted grid graph

Delete a subgrid of $m_0(n-2)$ vertices, $m_0 \leq (n-2)$, for embedding the 3-SAT graph later. Finally, to get the MSGG, add $2n^4$ vertices to the two topmost lines (L_3 and L_4) each and $25n^8$ vertices to the two rightmost lines (L_1 and L_2) each.

Modified slanted grid graph

Modified slanted grid graph

Theorem

Every modified slanted grid graph has a unique visibility embedding up to the preservation of lines.

The proof of this lemma consists of a strengthening of the following lemma.

Lemma

Let G be a PVG with visibility embedding ξ . Let L be a line in ξ such that (i) there are I points on L, and (ii) k points not on L. If $l \ge (k+3)^2$ then L is preserved in every visibility embedding of G

Proof sketch

Let the initial embedding of G containing L be ϕ . Consider another visibility embedding ϕ' where L is not preserved. There can be the following cases for ϕ' :

- **1.** All points of *L* are collinear in ϕ' .
 - a Their order is not preserved.
 - **b** Their order is the same, but som other points are also collinear with them.

(日) (日) (日) (日) (日) (日) (日) (日)

- **2.** Not all points of *L* are collinear in ϕ' .
 - a At least some k + 3 points of L are collinear in ϕ' .
 - **b** At most k + 2 points of L are collinear in ϕ' .

Proof sketch

Case 1 a: All points of L are collinear in ϕ' , but their order is not preserved. This is not possible because some visibilities disappear while some new visibilities appear.

- 日本 - 4 日本 - 4 日本 - 日本

Proof sketch

Case 1 b: All points of L are collinear in ϕ' in the same order, but some other points are also collinear with them. This is not possible because any point outside of L must see at least I points, while any point on L can see only at most k + 2 points.

Proof sketch

Case 2 a: Not all points of *L* are collinear in ϕ' , and at least some k + 3 points of *L* are collinear in ϕ' (say, on line *L'*). The point of *L* closest to this *L'* sees at least k + 3 points. Since this point can see at most 2 points of *L*, it must see k + 1 points that are not in *L*.
Proof sketch

Case 2 b: Not all points of L are collinear in ϕ' , and at most k + 2 points of L are collinear in ϕ' . Then a point of L must have at least k + 4 rays emanating from it containing all the other points of L. So the point must see at least k + 2 points not on L.

► A modified form of this lemma is applied twice on an MSGG to give the proof of the theorem. Hence the MSGG has O(n⁸) vertices, as the original grid has O(n²) vertices.

(日) (日) (日) (日) (日) (日) (日) (日)

- ► A modified form of this lemma is applied twice on an MSGG to give the proof of the theorem. Hence the MSGG has O(n⁸) vertices, as the original grid has O(n²) vertices.
- The deleted subgrid of the MSGG can be replaced with another gadget, such that the resultant graph can have only a limited number of visibility embeddings.

(日) (日) (日) (日) (日) (日) (日) (日)

The position of a point of the gadget can be controlled by its visibility relationship with the MSGG.

<ロト < 回ト < 回ト < 回ト < 回ト = 三日

The position of a point of the gadget can be controlled by its visibility relationship with the MSGG.

<ロト < 回ト < 回ト < 回ト < 回ト = 三日

Recognition Problem 3-SAT graph

- 1. We construct a gadget called the *3-SAT graph* to embed in the deleted subgrid of an MSGG.
- **2.** For any given 3-SAT formula θ , a 3-SAT graph of polynomial size can be contructed in polynomial time.
- **3.** The 3-SAT graph can be strategically embedded in a large enough MSGG, which is again of polynomial size with respect to the size of the 3-SAT formula.

3-SAT graph

- Once combined with the MSGG, each point of the 3-SAT graph can be embedded only in a definite horizontal line of the grid, while there might be a choice for the vertical line.
- After the 3-SAT graph is combined with the MSGG, it is divided into vertical strips called variable regions and clause regions, corresponding to the variables and clauses of θ.
- The red points represent the assignment of 0 or 1 to a variable in θ. A red point is embedded in the left of a variable region if the variable is assigned 1, otherwise it is embedded in the middle of a variable region if the variable is assigned 0.

3-SAT graph

- According to their placement, each red point is to be blocked from some yellow points that represent the occurrance of a variable in a clause.
- These blockings are possible only by green points, that can be embedded only on two vertical lines, one in a variable region and the other in a clause region.
- Each clause region has a blue point that needs to be blocked from a black point vertically above it. This blocker must also be a green point. A visibility embedding is possible only when each blue point has at least one green point as a blocker. If an assignment is not satisfying then some blue point does not have a green point as a blocker.

3-SAT graph

Reduction graph

The reduction graph has a visibility embedding if and only if the corresponding 3-SAT formula has a satisfying assignment.

Theorem

The point visibility graph recognition problem is NP-hard.

We consider graph optimization problems defined on the PVG of a given set of points in the plane.

Theorem

The problems of Vertex Cover, Independent Set and Maximum Clique remain NP- hard on point visibility graphs.

Given a graph G(V, E), we transform it to a PVG G'(V', E').

▲ロト ▲園 ト ▲ 臣 ト ▲ 臣 ト 一 臣 - つへぐ

▶ If G is a PVG but not a path, then G has a Hamiltonian cycle.

Given G and a visibility embedding of G, a Hamiltonian cycle in G can be constructed in linear time (Ghosh and Roy, 2015).

The whole graph including edges is given as input, and so the gift-wrapping algorithm takes only linear time, as we first find one convex hull vertex and then go through its edge list to find the next convex hull vertex.

Basic concepts

 $P = \{p_1, p_2, \dots, p_n\}$ is a given set of points in the plane.

▲ロ ▶ ▲ □ ▶ ▲ □ ▶ ▲ □ ▶ ▲ □ ▶ ● ○ ○ ○

Basic concepts

A partition of *P* into subsets S_1, S_2, \ldots, S_j is a *cycle partition* of *P*, when the points of each S_i can be joined by straight line segments to form a simple polygon i.e. no line contains all points of S_i .

Basic concepts

A cycle partition of a point set is *disjoint* when no two of the polygons enclosed by the cycles intersect with respect to vertices, edges or area.

▲ロ ▶ ▲ □ ▶ ▲ □ ▶ ▲ □ ▶ ▲ □ ▶ ● ○ ○ ○

Basic concepts

A *disjoint triangle partition* of P is a disjoint cycle partition of P where all the cycles are triangles.

- 日本 - 4 日本 - 4 日本 - 日本

Basic concepts

 We characterize planar point sets that admit a disjoint triangle partition and provide a polynomial time algorithm to construct such a partition, if it exists.

Basic concepts

- We characterize planar point sets that admit a disjoint triangle partition and provide a polynomial time algorithm to construct such a partition, if it exists.
- Given a set S of cycles, we characterize planar point sets that admit a disjoint partition into cycles of S and provide a polynomial time algorithm to construct such a partition, if it exists.

We say that two points p_i and p_j of P are visible to each other if the line segment $p_i p_j$ does not contain any other point of P.

A subset I of P such that no two points of I are visible from each other is called an *independent set* of P.

(日) (日) (日) (日) (日) (日) (日) (日)

Theorem

A set P of 3n points in the plane admits a disjoint triangle partition iff P does not contain an independent set of size n + 1.
